DATASET: Primary school – cumulative networks

This dataset is from our research on contact networks in primary schools, which was published in the paper High-Resolution Measurements of Face-to-Face Contact Patterns in a Primary School. Two weighted networks of face-to-face closeness between students and teachers make up the dataset. A daily contact network is supplied for each day of the research, with nodes representing persons and edges representing face-to-face contacts. Nodes contain two attributes: classname, which identifies the relevant individual's school class and grade, and gender. The "Teachers" class contains all of the teachers. Edges between A and B have two weights: duration and count. Duration is the amount of time A and B spent in face-to-face proximity over the course of one day, measured in seconds (multiples of 20 seconds); count is the number of times A and B made contact throughout the school day. The networks are given as two GEXF files, one for each day of the research, that may be put into Gephi directly.

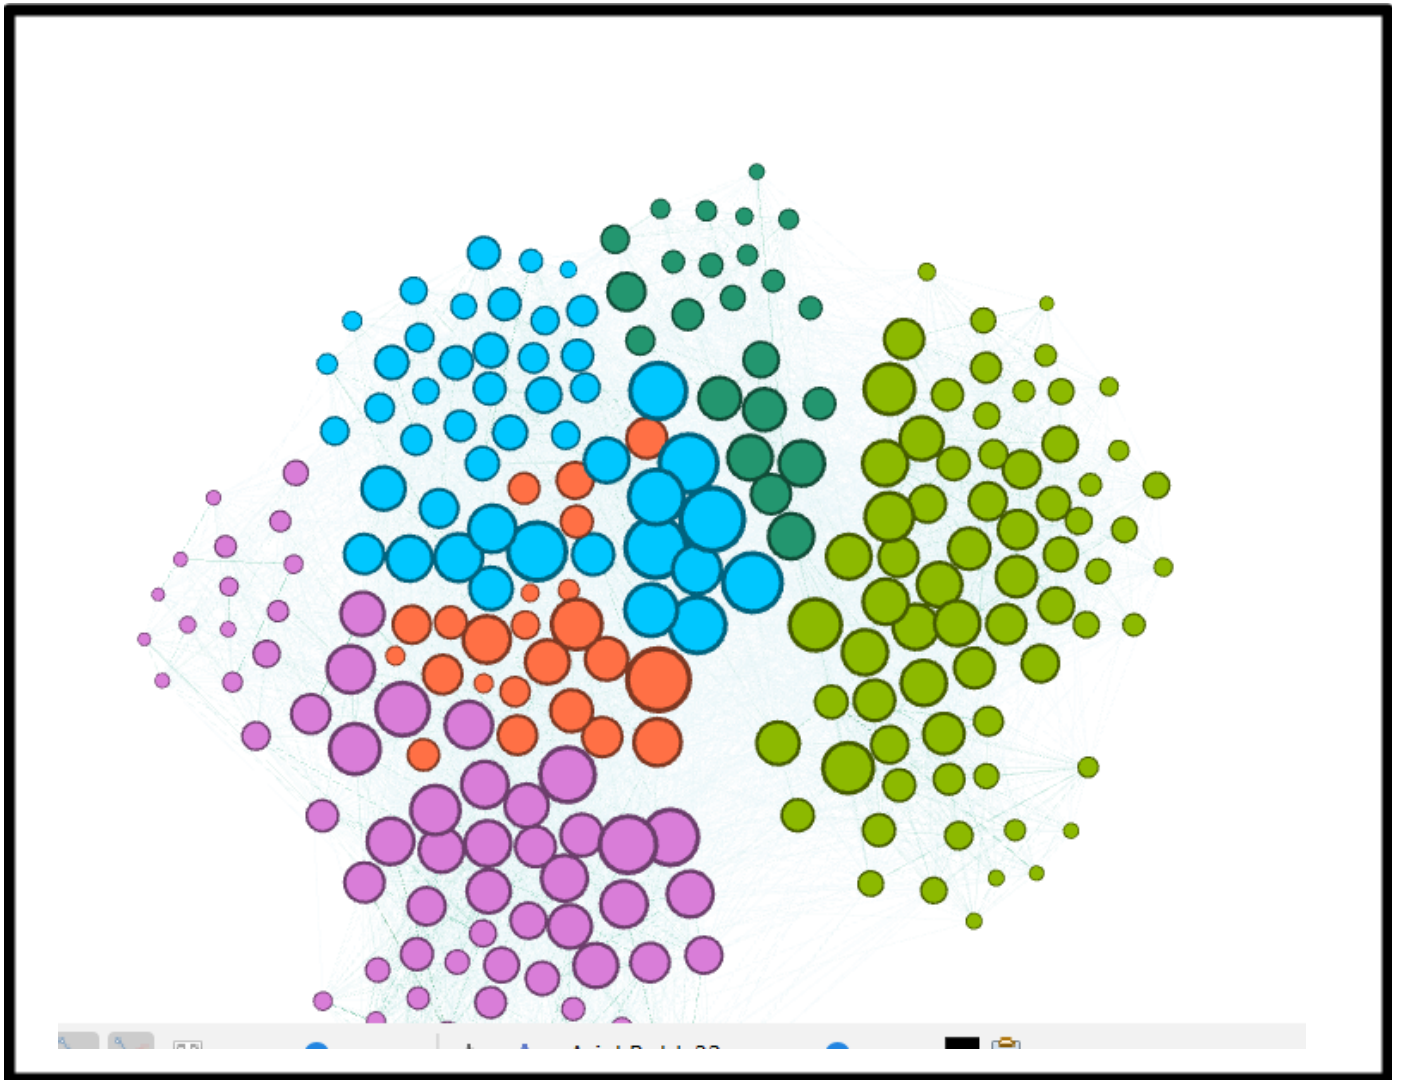

Modularity Class in Ranking

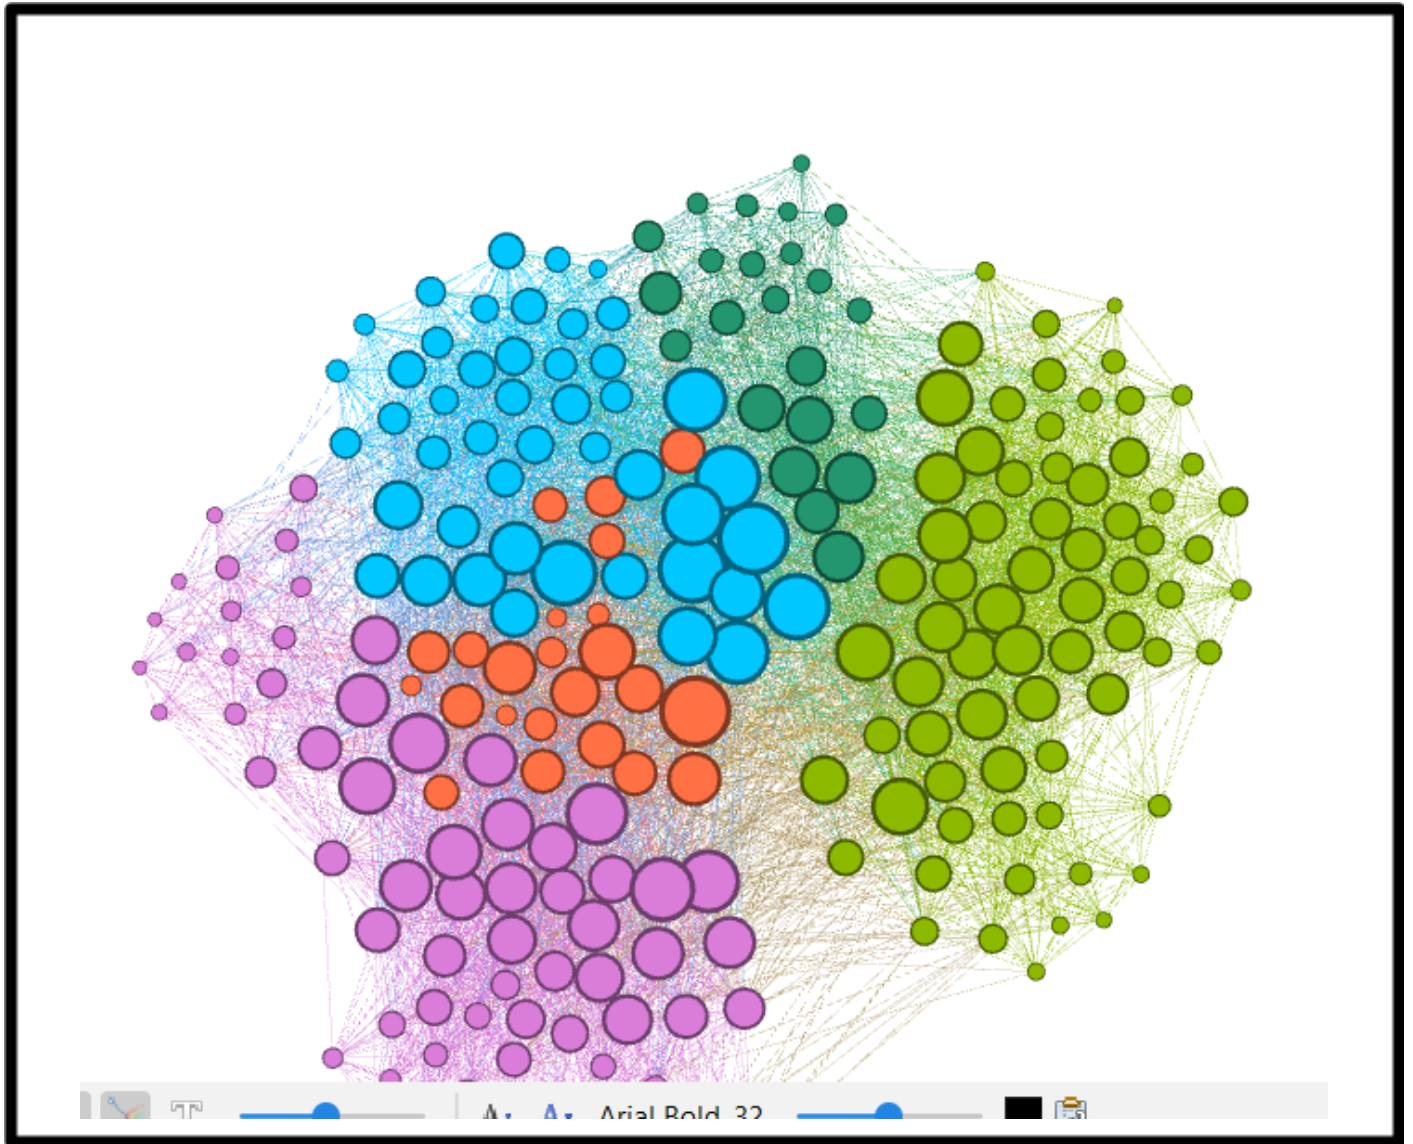

Edges Partition Count

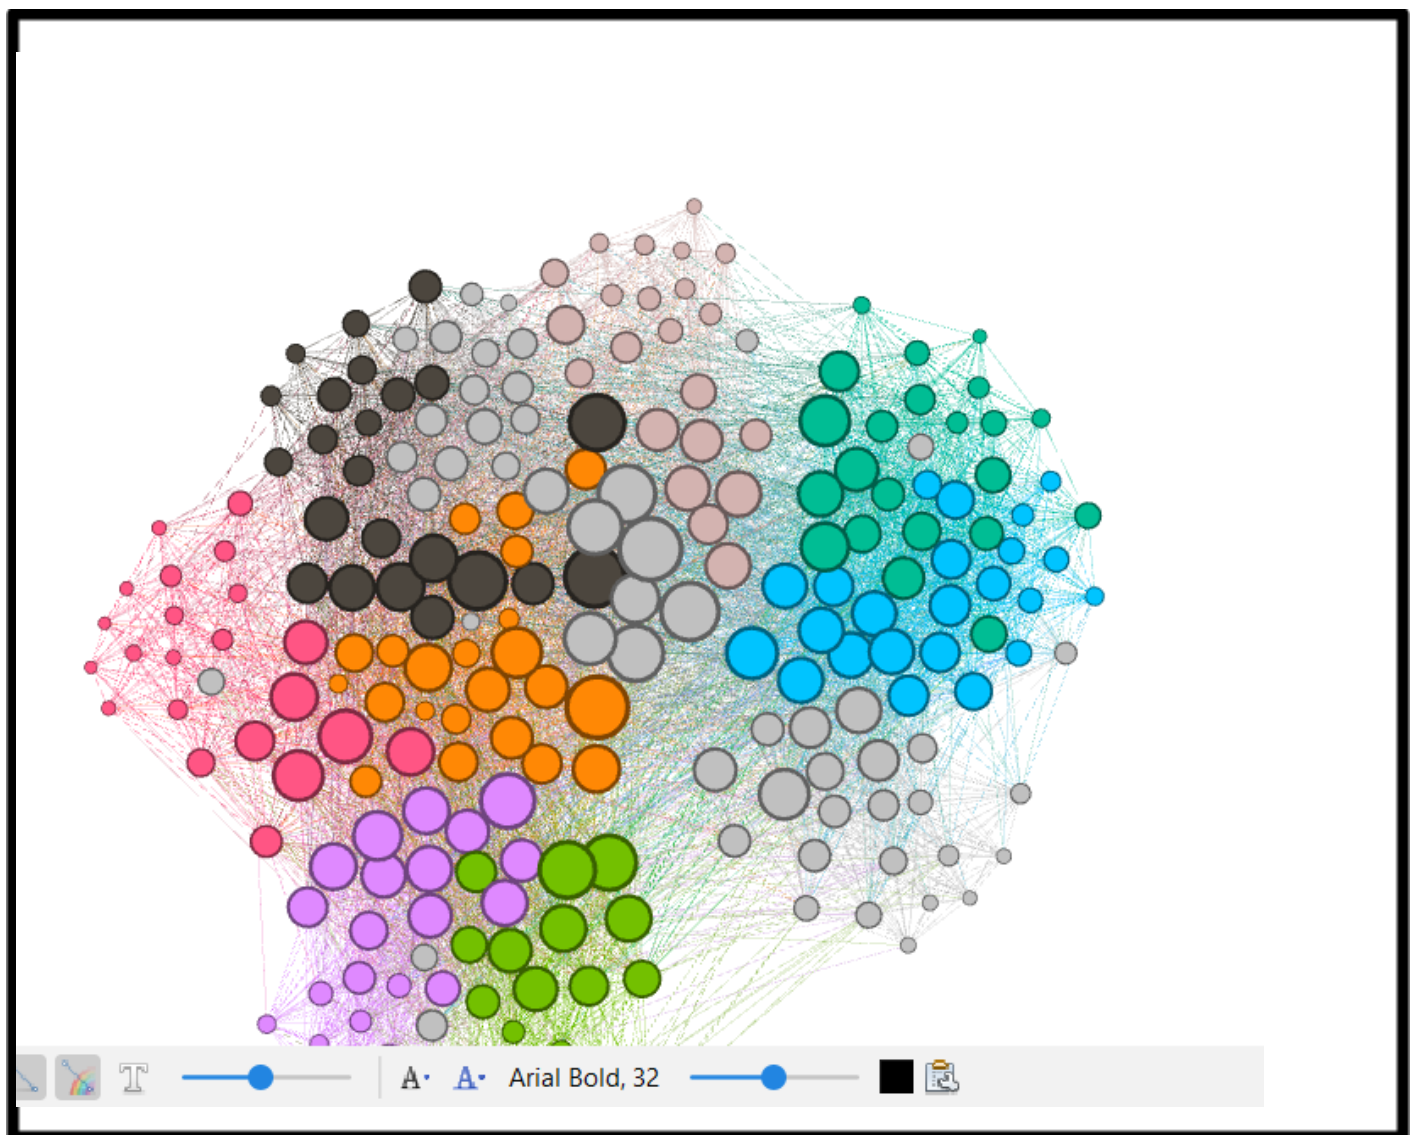

Edges Ranking Weight

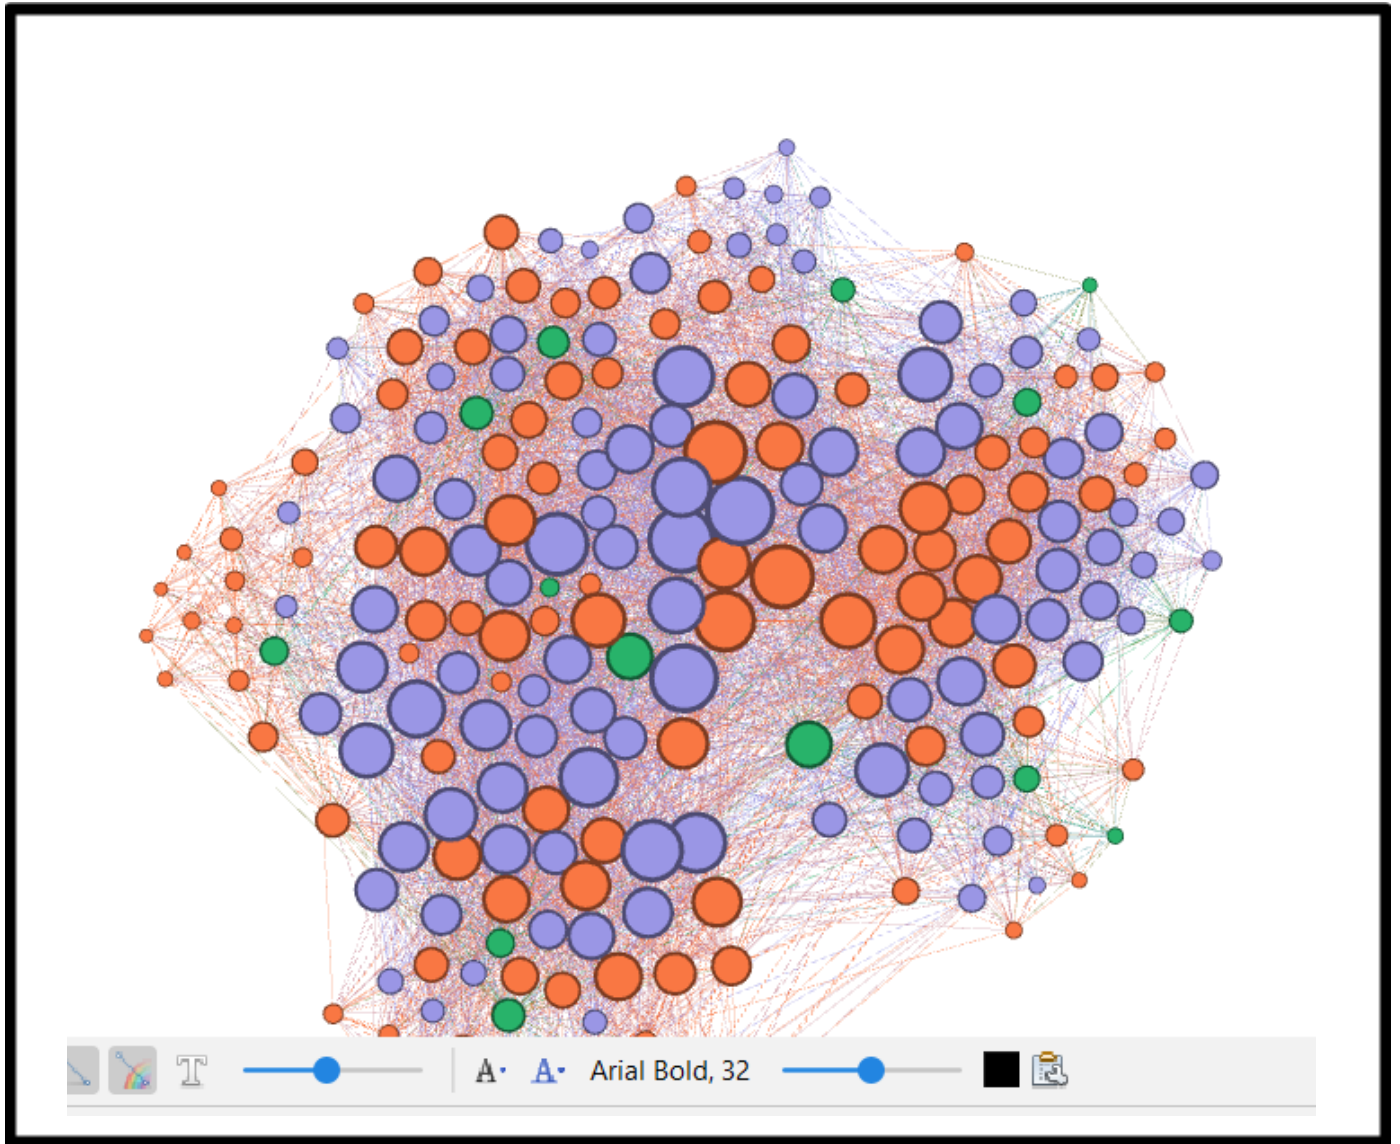

Edges Ranking Count

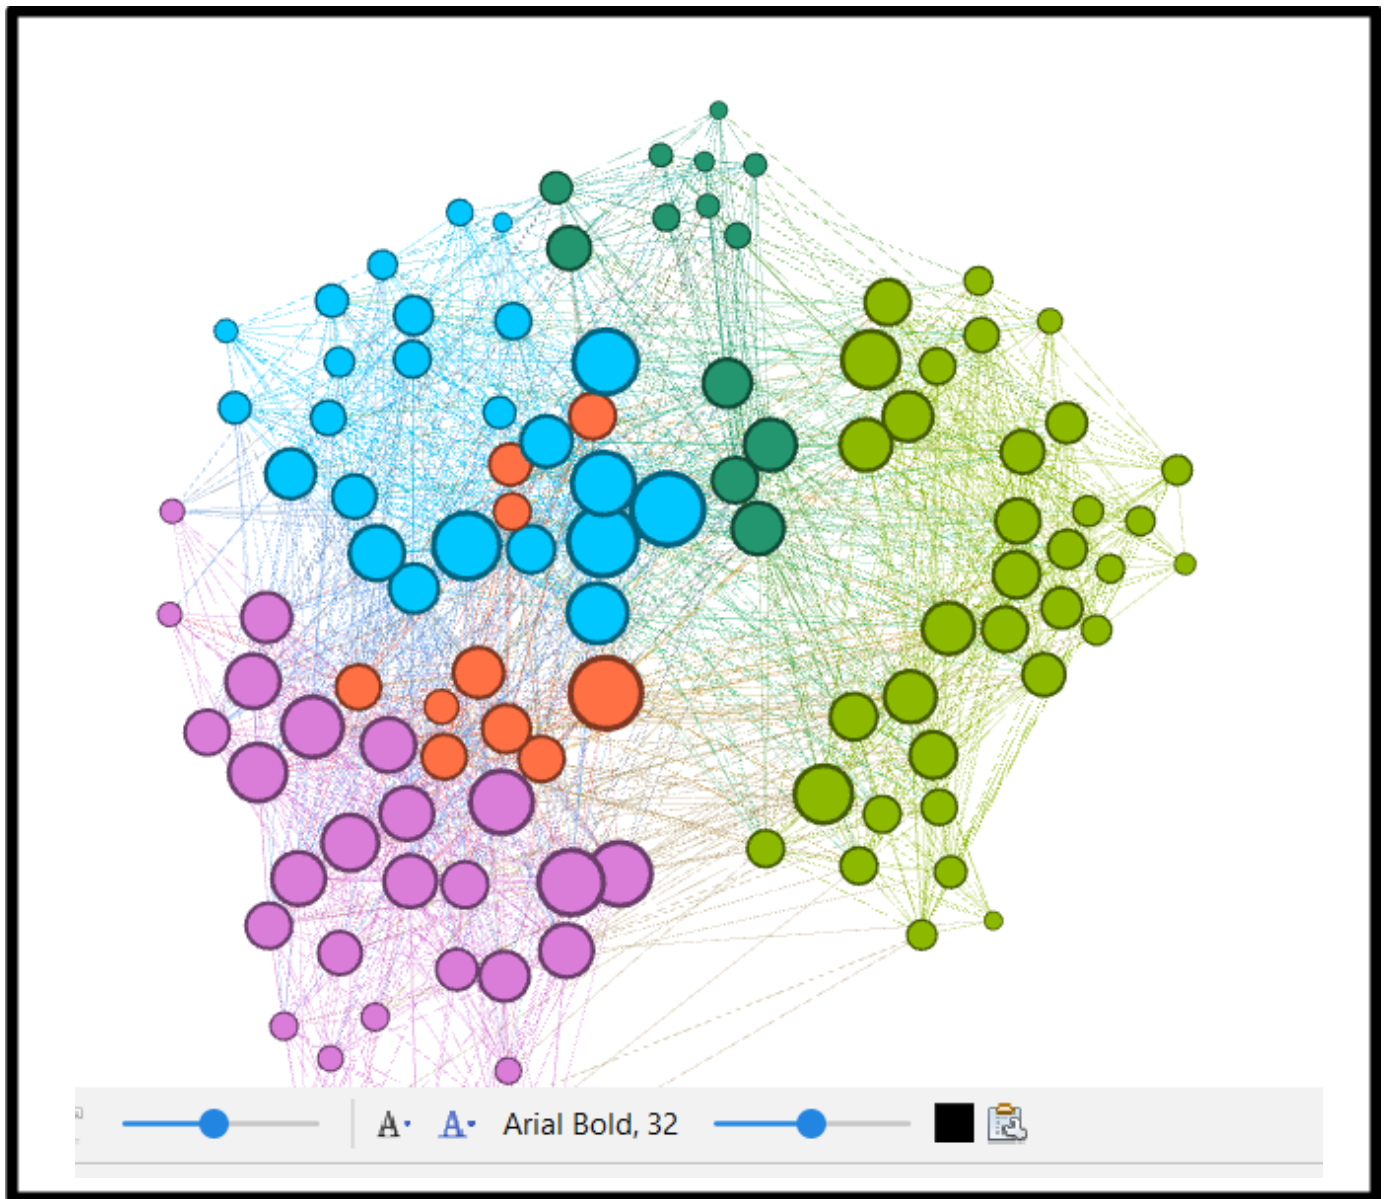

Very minor changes in edge through edge weight

Nodes partition classname

Nodes Partition Gender

Filter partition gender male and female
